Eleri Morgan-Jones, Research Assistant I, NARC, Havre
Darrin L. Boss, Animal Scientist, NARC, Havre
Robert N. Stougaard, Weed Scientist, NWARC, Kalispell
Cooperating Dealers and Manufacturers

OBJECTIVES:

It is the objective of this project to evaluate air drill openers and systems for the production of cereal grains under varying cropping conditions and systems in northern Montana.

From crop year 1997 through crop year 2004, the project was limited primarily to evaluation of “double-shoot” air drill openers using a research-scale ‘Concord’ air drill provided by Northern Ag Service of Malta, Montana with opener hardware provided by various cooperating manufacturers and dealers.

Beginning in crop year 2005, project investigations were expanded to include comparison of seed and fertilizer placement configurations via “double-shoot opener” and “mid-row bander” systems using loaned “Bourgault” commercial-scale air seeder and air till drill equipment provided for research purposes by Bourgault Industries Ltd and supported by Tilleman Motor Company of Havre, Montana with opener hardware provided by various cooperating manufacturers and dealers. The ‘Bourgault’ trial was not conducted in 2008 due to an equipment change and associated retrofitting being too late in the spring season to accomplish timely planting.

RESULTS:

On-Going Opener Studies Conducted with the ‘Concord’ Air Drill:

The agronomic performance of six “double-shoot” opener configurations under dryland chemical fallow conditions with ‘Choteau’ spring wheat direct-seeded into spring wheat stubble at Havre in 2008 is presented in Table 1. These evaluations are normally conducted using the ‘Concord’ air drill with seeding rate and overall fertilizer rate (70-40-25) held constant on a 12-inch shank spacing. However, initial soil nitrogen and other nutrient inventories were such that the traditional applied fertility program was not carried out for this study in 2008. Thus, no fertilizer was applied; and the openers were evaluated only for their seed placement characteristics and resulting crop performance. Statistically significant differences among treatments for the response variables measured included Stand Percent, Row Style, Seed Band Width, Plants/SqFt, Fertile Culms/Plant, Head Date and Grain Moisture. Under 2008 conditions there were no statistically significant differences among treatments for Culms/SqFt, Plant Height, Yield, Test Weight, Kernel Weight, Grain Protein, or Sawfly Cutting.

Yield performance data for all such opener trials conducted at Havre by NARC-Agronomy since the air drill investigations began in 1997 are presented in Table 2. A “10-Year, Comparable Average” summary for all openers evaluated in at least three of the ten years (1998-2008) with spring wheat on mechanical or chemical fallow at Havre is presented in Table 3. ‘Concord’ air drill data for crop year 2005 is not included due to an equipment malfunction (not associated with the openers themselves) that variably impacted opener performance. Figures 1 through 6 comprise an opener and post-harvest photo gallery for spring wheat plots established with openers evaluated in 2008. See reports from previous years for data and photo galleries associated with other openers evaluated over time.

SUMMARY:

Producers contemplating purchase of an air drill logically base their decisions on a number of variables to include manufacturer, dealer support, features, availability, price, etc. A decade ago, limited attention was given to the type and style of interchangeable openers supplied with a new or used air drill. In some situations, dealers want to encourage a prospective buyer to consider a particular type of opener thought to be most appropriate for the grower’s...
own conditions and needs, but they may be reluctant to do so if less sophisticated and less costly openers being selected on a competitor’s machine would result in loss of a sale. Due to the cost associated with outfitting a machine of average width with openers, producers prefer to limit their on-farm inventory to one or at the most perhaps two differing scenarios to cover nearly all planting needs. Openers range widely in cost, but it is not uncommon for producers to spend an average of $100-$150 per shank which amounts to $4,500-$7,500 or more for a typical air drill. Thus, few producers can afford to make very many selection mistakes in a “trial and error” approach before finding the opener and placement configuration most appropriate for them. It is estimated that approximately 70% or more of the dryland wheat and barley in major producing areas of Montana is sown with air drills. Thus, producers are keenly interested in unbiased evaluation of air drill opener and system options.

Our involvement with air drill opener investigations began in 1997 when Northern Agricultural Research Center hosted the third Montana “Fields of Tomorrow” show sponsored by Monsanto Company and KMON Country Radio with trade show support of numerous other vendors of agricultural supplies, equipment and technology. Part of NARC’s contract for hosting the show included on-site evaluation of air drill openers. The use of a research-scale ‘Concord’ air drill was provided to Northern Agricultural Research Center by the manufacturer in cooperation with area dealer, Northern Ag Service of Malta. At the same time, a research-scale ‘Conserva-Pak’ air drill was purchased by MSU for use in conducting a series of large-scale cropping systems projects in Montana funded by USDA’s Special Grant Program. Initially the MSU unit was available for inclusion in the opener evaluation studies at Havre and Moccasin. Use schedules with other projects at two different research centers have since limited the use of the Conserva-Pak in specific seed and fertilizer placement investigations. Carlson has conducted air drill opener investigations each year since 1997 with the Concord machine. Manufacturers and/or dealers provide all opener hardware at no cost to the Research Center in exchange for development of unbiased performance evaluation information.

Square-wall, 6-inch wide ‘Titan’ pneumatic packer tires/wheels were utilized with all openers in 2001-2008 trials with the Concord machine. Standard 165x15R radial pneumatic packer tires/wheels were utilized with all openers in previous Concord trials. The wider Titan packer tires afford more appropriate packing with opener scenarios featuring wider seed bands, but may be less appropriate than narrower packer tires for packing narrow seed band scenarios. Interchanging packer wheels/tires in addition to the openers themselves for different openers configurations within a single trial is not feasible in view of the time and effort required when for experimental standardization all planting treatments must be imposed within a single day.

The Concord unit has also been integral to other research investigations conducted by Stougaard and Carlson involving the use of widened seed bands and increased rates of seeding for reduction of wild oat competition in the production of spring wheat. Carlson, Lamb, Stougaard and Whitmus are further involved in developing other crop and crop pest management strategies utilizing Variable Rate Technology (VRT) equipment added to the Concord with funds provided in part by the Montana Wheat and Barley Committee, Northern Agricultural Research Center and Northern Ag Service. Boss, Carlson and Lamb utilized these technologies in yet a fourth collaborative effort where they investigated the effects of barley class, variable seed band widths, variable seeding rates, and variable harvest end points on both forage and grain end use parameters.

The Bourgault equipment, consisting of the center section of a commercial-scale Bourgault 5710 Air Hoe Drill equipped with Series 25 Md Row Banders and a three-compartment Bourgault 5350 leading air seeder/cart, was delivered to the research center in 2005 on loan for research purposes by Bourgault Industries Ltd at Minot, ND with local dealer support provided by Tilleman Motor Company of Havre.

Growers are generally aware that there are limits with respect to the amount of actual N+K₂O that can be delivered together with seed before germination and seedling damage will occur. Older guidelines were developed via research conducted at a time when the principal granular nitrogen fertilizer source was Ammonium Nitrate. With Urea now being the most commonly used granular nitrogen fertilizer product, newer guidelines call for lower limits. In MSU’s 2005 Extension Bulletin 161 (“Fertilizer Guidelines for Montana Crops”) http://msuextension.org/publications/AgandNaturalResources/EB0161.pdf, the following statement appears under “Special Conditions” for spring and winter wheat fertilization:

*Drill-row applications of N+K₂O should not exceed 20 lbs/a. When using Urea as the N source, drill-row application of N+K₂O should not exceed 10 lbs/a with a 6-7 inch row spacing. When using a wider spacing, do not apply any urea with the seed. With newer drills and openers, the mixture of seed, fertilizer and soil is much greater, so more fertilizer can be placed in the “row” due to the dilution of potential detrimental impacts*
from salts and ammonia on germination and growth.

Optimum seedbed moisture, finer-textured soils, and wider seed/fertilizer distribution bands can each serve to reduce such detrimental effects, but there are still limits. Reluctance to meet the additional investment cost for air drills with dual-air delivery systems is cause for some growers to employ broadcast fertilizer application practices or to “push the envelope” with respect to applying N+K2O fertilizers with seed.

The Bourgault equipment has made it more feasible to evaluate such seed and fertilizer relationships under conditions more equivalent to those dealt with by commercial growers. Germination and/or seedling damage associated with over-application of N+K2O fertilizers delivered with seed is not always obvious via casual observation of stands. It is interesting to note that in the 2006 study reported previously – the number of Plants/SqFt was reduced by 29 percent when applying 30-40-0 with seed and 40-0-0 via pre-plant broadcast in comparison with plant populations achieved with the same seeding rate and seed openers where the entire 70-40-0 fertilizer application was placed via mid row banders. In 2006, this same treatment involving over-application of N+K2O with seed resulted in a 23% wheat plant population reduction in comparison to the overall average population achieved by the other seven treatment configurations in the trial. In this case, yield was not significantly reduced since the population reduction resulted in compensation with a greater number of fertile culms per plant. It is likely that such could not always be expected to occur. In 2007, even though higher rates of intentional "over-application" of urea nitrogen in direct contact with seed were employed; early plant development stages were favored by above normal precipitation likely serving to avert germination and seedling damage that would have otherwise been expected to occur.

FUTURE PLANS:

The Research Center plans to continue work with traditional opener evaluations using the Concord unit in response to continued interest expressed both by Montana and out-of-state producers. New opener configurations have been incorporated into the trials during several of the past five years, and after-market mid-row fertilizer banding capability was added in 2001 for investigations with this unit. The Concord drill lends itself to easier head-to-head comparison of numerous sets of primarily "double-shoot" openers since changeovers involve only ten shanks and replicated plots can be established within a relatively small research area.

The new three-product compartment Bourgault equipment affords opportunity to further expand evaluations relative to nutrient delivery and placement. Primary initial emphasis will be placed on replicated comparison of low disturbance seed placement and fertilizer placement via mid banding versus seed and fertilizer placement with leading "double-shoot" opener systems. And, given the steep increases in cost of fertilizer materials, effort will be made to address comparison of low disturbance seed and fertilizer placement systems versus single-shoot seeding coupled with broadcast fertilization. Special emphasis will be placed on further investigation of seed and seedling damage associated with delivering too much nitrogen and/or potassium fertilizer via the seed delivery stream.

Stougaard and Carlson completed the third of three years of field research in 2001 evaluating the effects of seeding rate and placement patterns on spring wheat’s ability to compete with wild oats. It was difficult to secure extramural funding support for the pilot studies in this effort. With positive results from the pilot studies in hand, the next phase will logically involve replicated, commercial field-scale application of the technology in the presence of ‘already-established’ wild oat populations. It will not be possible to carry out the next phase of this research without an appropriate level of extramural funding from some yet unsecured source.

Carlson, Lamb and Whitmus will continue other existing investigations underway with VRT-equipped air drills in site-specific placement of nitrogen for optimized yield and protein relationships in wheat.

Boss, Carlson and Lamb completed the third of three years of field research in 2003 on, “Increasing Yield and Management Options for Producers who Traditionally Plant Barley for Forage or Grain Production.” Thus, although originally put to work at Havre solely for the purpose of evaluating opener configurations, air drills have served multiple research endeavors out of the Havre station.

1/ Treatment Description Detail: (Due to high initial soil profile N inventories, no fertilizer nutrient was applied in 2008).

2/ Base Equipment = 10' (10-shank, research-scale) 'Concord' Air Drill with 12" Shank Spacing and 6" 'Titan' Square-Wall Pneumatic Packers.

3/ Average 'splayed' stubble width 4" above soil surface at harvest maturity.

4/ Based on means of multiple row counts. Culms = fertile culms (stems with filled heads).

5/ No. of Days from January 1 (192 = July 10).

6/ Volumetric yields are based on 60 lbs/bu as the standard test weight for wheat.

7/ Protein values are adjusted to 12 percent grain moisture.

8/ Sawfly Rating = Percent Stem Cutting.

*G.R. Carlson, Northern Agricultural Research Center, Havre - 2006 data lost to intermittent seed metering roller malfunction.

All openers are "double-shoot" configurations with target seeding rate at 60/lb/ac and fertilizer at 70N, 40P₂O₅, and 25K₂O via blended granular fertilizer at 25# product/ac (except 2008 at 0-0-0 fertilizer due to residual soil N inventory).

1/ See separate reports for individual investigations by year for additional performance parameters, site & climatic specifics and project management details.

2/ Only the most recent 7 years data are shown, but summary calculations include all years noted (2005 data lost to equipment malfunction).

3/ Percent of check entry yield performance for the same data years as those in which a given entry was tested.

4/ 10-Yr Comparable Average Yield = (x/y)^2 where x = average yield of a given entry for years tested, y = average yield for the Check Entry for the same years, and z = 10-Yr average yield for the Check Entry.

2005 data lost to intermittent seed metering roller malfunction.
