MONTANA
STATE UNIVERSITY
MONTANA AGRICULTURAL
EXPERIMENT STATION

OFF-STATION COOPERATORS - PRODUCERS - CES AGENTS

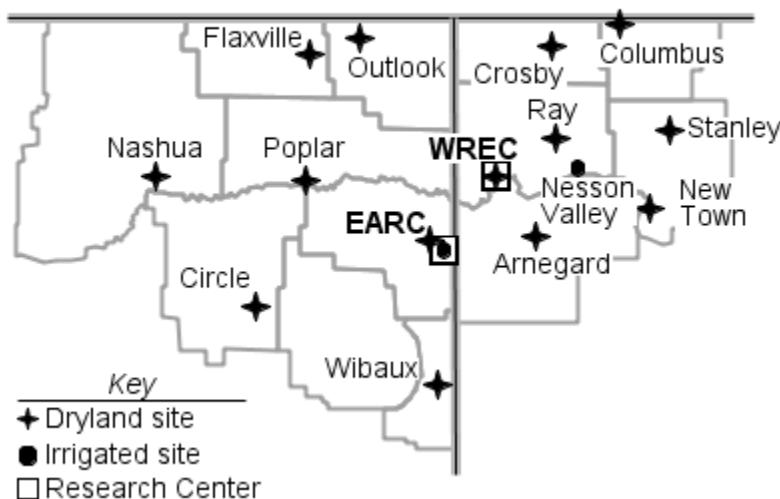

MONTANA

Circle – Victor Wagner – Agent Ken Nelson
Flaxville – Jeff Mohr – Agent Nicole Wrinkler
Nashua – Bill Lauckner – Agent Shelley Mills
Poplar – Mark Swank – Agent Ann Ronning
Wibaux – David Maus – Agent Dave Bertelsen
Outlook – Gordon Stoner – Agent Terry Angvick
Fairview – Phillip Hurley
Fairview – Rodney Hurley
Sidney – Russel Dige

NORTH DAKOTA

Arnegard – Milo Wisness – Agent Dale Naze
Columbus – Mitch Strom – Agent Dan Folske
Crosby – Harlan Johnson – Agent Keith Brown
Nesson Valley – Bill Sheldon – Potatoes
New Town – Jerry Pennington – Agent Jim Hennessy
Ray – Keith Daniel – Agent Warren Froelich
Stanley – Wayne Johnson – Agent Jim Hennessy

Location of Test Sites

We would like to take this opportunity to thank the County Agents, the County Ag Improvement Associations and especially the farm operators who permit the location of off-station plots on their land at no cost. ***All are to be commended for their cooperative efforts in helping determine crops and variety performance in the MonDak region.***

Results from tillage, chemical fallow, and field scale no-till trials, as well as other management trials on other dryland and irrigated crops can be obtained by visiting with Center personnel.

Refers to developer: CDC = Crop Development Center, University of Saskatchewan; AC = Agriculture Canada;

GM = General Mills, WB = WestBred, ID = University of Idaho

²R =resistant; MR =moderately resistant; M =intermediate; MS =moderately susceptible; S =susceptible; VS =very susceptible;
NA = data not available. *Indicates yield and/or /quality have often been higher than expected based on visual head blight symptoms alone.

All experiments are statistically designed so that the “real” yield differences can be separated from yield differences that occur by chance. LSD (Least Significant Difference) values are used for this purpose. When comparing the yield of another variety, the yield difference must exceed the LSD value (higher or lower) to be considered a “real” difference. It is advisable to use multi-year averages when choosing a variety or cropping sequence.

Wheat Variety Comparisons --- Williston, ND

Column "\$/A" was arrived at by calculating a gross per acre income for each variety using market price and protein premiums obtained on Dec. 2, 2010. The base price for 14% protein wheat was \$7.44, and for terminal durum was \$6.35. All spring wheat varieties are compared to Glenn and durum varieties to Mountrail on a plus or minus \$/a basis.

¹ Refers to developer. WB = WestBred. DGP = Dakota Growers Pasta.

² R = resistant, MR = moderately resistant, M = intermediate, MS = moderately susceptible, S = susceptible, VS = very susceptible,

NA = data not available. All varieties are resistant to current stem rust races.

³ Number seeds/lb: Large = less than 11,000; medium = 11,000-12,000; small = more than 12,000

* Indicates yield and/or quality have been higher than would be expected based on visual head blight symptoms alone.

| Montola 2000 | MT/ND | yes | N | high oleic | m good | good | med | good | early | MS | MS |
| Montola 2001 | MT/ND | yes | STP | high oleic | good | fair | med | good | med | MT | MT |
| Montola 2003 | MT/ND | yes | N | high oleic | v good | v good | m high | good | m early | MT | MT |
| Montola 2004 | MT/ND | yes | N | high oleic | good | good | m high | good | m early | MS | MT |
| Morlin | MT/ND | yes | STP | high linoleic | v good | good | med | good | m late | T | T |
| Nutrasaff | MT/ND | yes | RED | linoleic | good | good | med | high | med | T | MT |

¹ STI = Safflower Technologies International, MT = Montana, ND = North Dakota

² STP = striped, N = normal, RED = reduced

³ Lino - linoleic

⁴ Relative ratings of yield, test weight, and oil will vary under conditions of moderate-severe disease infestation

⁵ Alt = Alternaria leaf spot disease, BB = bacterial blight, S = susceptible, MS = moderately susceptible, MT = moderately tolerant, T = tolerant

⁶ "yes" indicates the variety is protected and the seed may be sold for planting purposes only as a class of certified seed (Title V option)

Development of Durum Varieties for the MonDak Region

J. Eckhoff¹ and E. Elias²

Cadmium (Cd) is a nonessential heavy metal that may cause health problems for some people. Diet is the main source of Cd for nonsmokers, with cereal products, including durum, accounting for up to 20% of the daily intake of Cd. The current official standard for maximum level of Cd in wheat grain as stated by the Codex Alimentarius Commission (a part of the World Health Organization), is 0.2 ppm, and the European Union has adopted this level of Cd as the maximum allowed in domestic and imported durum.

Cadmium levels were screened in durum grain samples from plots grown across Montana in 2005. Sites included research centers and several off-station sites in eastern Montana. Cadmium levels ranged from 0.055 ppm to 0.259 ppm. Soil characters affect the amount of Cd taken up by durum. Additionally, genetics play a role in accumulation of Cd in the grain. Most durum genotypes grown in Montana accumulate Cd in the grain. A low Cd-accumulation trait does exist in durum and is caused by a single dominant gene.

Europeans have traditionally purchased durum from the desert Southwest. That area is no longer a reliable source of durum because of urban sprawl and decreasing water availability. Additionally, southwest durum often has a high amount of cadmium. European durum buyers are looking for another source of high quality durum with low Cd levels. Montana and North Dakota produce high quality durum, and may fill the market required by European durum buyers. Because of the European Union's restriction on Cd levels in imported durum, incorporating the low Cd-accumulating character has become a top priority. One Canadian variety has been identified as having low Cd accumulation. Several dozen lines from the CIMMYT (International Maize and Wheat Improvement Center) program were evaluated for Cd accumulation and quality. A total of 11 lines with low Cd accumulation and good quality were identified. Emasculated crosses were made using high quality lines as female parents and low Cd-accumulation lines as male parents in 2007. Currently we have 83 low-Cd F6 lines growing in the greenhouse. These will be selected next year for yield evaluations in the following year.

Eighty-four solid-stemmed lines from the World Collection were identified in 2004 and crossed onto a male sterile facilitated recurrent selection population in 2005 to develop a solid-stemmed population. This solid-stemmed population has been continued and maintained using solid stemmed, high quality, and low Cd-accumulating lines as male parents. Plants were selected from the F2 population based on stem-solidness and other agronomic characters. We currently have 35 F7 solid-stemmed lines that will be evaluated for yield in 2011.

* dry weight basis

Removing hulls from normal hulled feed and malt barley lines did not reduce starch yield per acre. About 10.2% of grain yield was lost to dehulling, but percent starch of the dehulled material was almost 6% greater. Dehulling did not remove starch.

Using Zinc to Reduce Cadmium Accumulation in Durum Grain

J. Eckhoff¹

Cadmium (Cd) is a nonessential heavy metal that may cause health problems in some people. Diet is the main source of Cd for nonsmokers, with cereal products, including durum, accounting for up to 20% of the daily intake of Cd by adults. The current official standard for maximum level of Cd in durum wheat grain as stated by the Codex Alimentarius Commission is 0.2 ppm (2) and the European Union has adopted this level as the maximum allowed in domestic and imported durum. Other durum buyers may also adopt this maximum level.

Cadmium levels were screened in durum grain samples from plots grown across Montana in 2005. Sites included research centers and several off-station sites in eastern Montana. The Cd levels ranged from 0.055 ppm to 0.259 ppm.

Cadmium is found naturally in some soils. Soil characteristics, such as pH and chloride content affect Cd uptake. A greenhouse study conducted in Saskatchewan reported that zinc (Zn) applied to soil prior to planting significantly reduced Cd in durum plant tissue, while Zn applied foliarly at the four-leaf stage or at flowering had no effect on grain Cd concentration. The objective of this study was to evaluate the use of Zn to reduce cadmium accumulation in durum grain in the field.

Two experimental sites at the Eastern Agricultural Research Center were used, one on the dryland farm and one on the irrigated farm. Nitrogen and phosphorus were uniformly broadcast at rates determined by soil tests. Two varieties of durum were used, one that accumulates Cd in the grain (Alzada) and one that does not (Strongfield).

Treatments were 1) Zn applied with the seed in the form of zinc sulfate at a rate of 1 lb Zn/ac; 2) Zn applied with the seed in the form of zinc sulfate at a rate of 1 lb Zn/ac plus Zn applied foliarly at the boot stage as chelated Zn at a rate of 1 gal/ac (0.97 lb Zn/acre); and 3) no applied Zn. The chelated zinc was EDTA 9% chelated zinc.

Data were analyzed across the three years for each site. The zinc treatments had no effect on grain yield, test weight or grain protein content on either the dryland or irrigated sites. Zinc applied with the seed had no effect on grain cadmium or zinc content. Chelated Zn applied foliarly at the boot stage reduced grain cadmium content by about 25% at the dryland site and by about 13% at the irrigated site. Grain cadmium content was reduced similarly in both varieties. The Cd level dropped from above the 0.2 ppm limit to below that limit on the dryland site.

Grain yields, test weights, grain protein, grain cadmium and grain zinc content of durum grown at the dryland and irrigated sites and averaged across three years (2007-2009).

| Treatment | Variety | Dryland site | | | | | Irrigated site | | | | |

Irrigation Research at Nesson Valley 2010

Tyler Tjelde¹

Greetings, well another growing season has seemed to fly by, but one that didn't go unnoticed. I believe this could be my eulogy referencing Nesson Valley for years to come. This would be obvious to most people, but in three years I have come to the conclusion that there are certain things that you absolutely cannot control and Mother Nature and research, well they don't always co-exist. It only took an M.S. in Agronomy to figure that out. Overall it was a very productive year and each year I get more excited for the next.

The Nesson Valley project continues to expand as we are in the process of converting the third linear to an automated Variable Rate Irrigation (VRI) system. Developing this linear system will give us another 35 irrigated acres to expand our research at the Nesson site from 70 acres to 105 acres and allow us to conduct irrigated research on each of the three linear systems every year. For those not familiar with the VRI system I will explain briefly. The VRI system divides the linear into 22 separate controlled banks (every 50 feet). Each bank can apply a different rate of water as the linear moves across the field allowing for a multitude of cropping systems. Without this, the linear system would only be able to apply one rate over the entire field. Again last year we had up to twelve different crops under one linear.

In 2010 we were excited to have the opportunity to use both water sources (surface and ground) and have set up an experiment on approximately 15 acres comparing both sources. This is one area of research that has not seen a lot of work over the years. This long-term project is very dependent on the lake level maintaining a level that we can pump from. We would like to look at each water source and what, if any, are the effects on soil properties and are there any production alterations that could alter plant growth.

Water is an important resource for high value crops in the MonDak region. Although it may not be a limiting resource for production in all regions of the state, it is vital to the MonDak region. In the past, producers viewed irrigation as an abundant, supplement water source with little incentive to conserve it. Now with water shortages becoming a concern in many parts of the country, there is an increase in awareness among producers to integrate more efficient irrigation practices into their farming systems to optimize production while sustaining water resources. At the Nesson Valley Research project we are looking at this not only in sugarbeet production but in wheat, barley, lentil, and potato. In the future we would like to look at additional crops.

Our vision at the Nesson Valley site is to further advance irrigation practices, improve crop production within an irrigated system and develop alternative cropping systems to improve water, nutrient and pest management. I encourage producers to contact me if you have any questions on what we are currently researching. I would also encourage anyone to share any ideas they may have for irrigated research so we can advance agronomic productivity for this region. Our goal is to improve production for you! The date for the 2011 Nesson Valley field tour is set for July 28th 2011. Look forward to seeing you there!

Comparing Tillage Systems (conventional, minimum, no-till) With Overhead Irrigation Using a 3 Year Crop Rotation of Corn, Soybean, and Barley (Nesson Valley 2010).

Tyler Tjelde¹

Objectives

This project examines the interaction between tillage systems and soil quality and the interaction between crop production and tillage to better understand the benefits of overhead irrigation on production and tillage. Questions that we hope to answer include how tillage is going to affect the quality of our soil and will this soil quality affect crop production when irrigation is involved. What are the benefits of selecting the proper tillage to match the specific crop? With things constantly changing, how can the interrelationships between crop rotation/production and tillage systems be defined?

Methods

Plots strips were 50 feet by 200 feet and replicated four times in a split block design. Fertilizer was spring-applied at recommended rates determined by soil testing. Weeds were managed with herbicides to minimize their impact on production. Percent residue cover, soil temperature, stand counts, grain yield, proteins, and test weights were measured. Tillage was done in the spring. Conventional tillage consisted of multiple passes with a disc and cultivators resulting in <30 % residue left. Minimum tillage varied based on previous crop. Corn residue was aggressively disked (5mph) cutting at a depth of 4 inches while still maintaining >30% residue cover. Barley residue was also disked but ground speed and depth were reduced to maintain the > 30% residue cover. A field cultivator was used to till the soil in soybean residue, leaving most of the residue on the soil surface. Only trash wipers (residue managers) were used in the no till system to move residue from seed row.

Results

| Corn Variety | A | B | A | B | A | B |
|----------------------------|---------|----------|-------------|--------|---------|--------|

Quantifying Water Use in Irrigated Sugarbeet Production on Sandy Soils

Nesson Valley 2010

James Staricka and Tyler Tjelde¹

Objectives

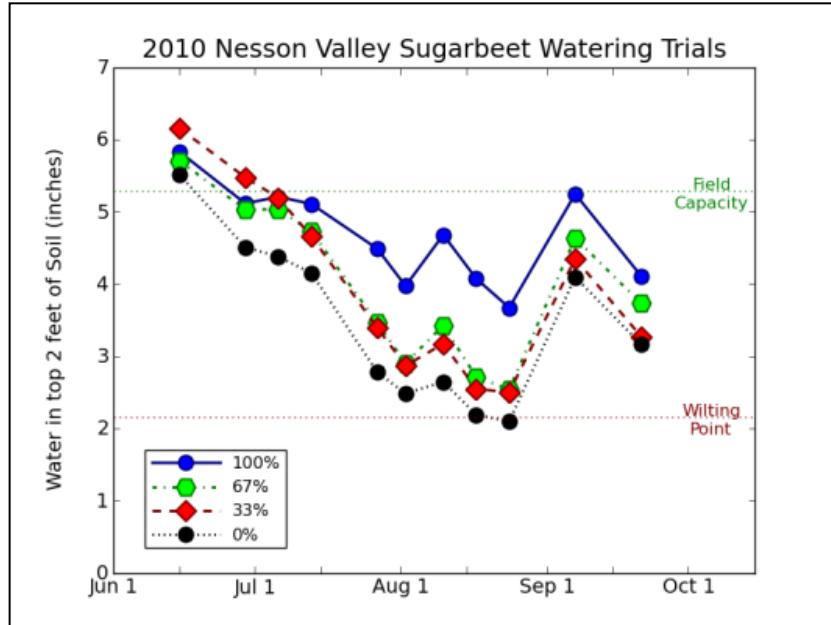

The objectives of this project are to investigate different irrigation rates in sugarbeet production to improve water use efficiency, determine critical stages of water use in sugarbeet production, and refine irrigation scheduling recommendations.

Methods

The experimental design is a Randomized Complete Block Design (RCBD) with four replications. Each plot will be 50 ft. by 60 ft. with watering rates randomized for each plot. The treatments consist of four irrigation rates (100%, 66%, 33%, 0%) and two sugarbeet varieties. Crop water use determined by using the North Dakota Ag Weather Network (NDAWN) and neutron probe moisture sensors. The irrigation rates determined using an irrigation scheduler (<http://ndawn.ndsu.nodak.edu>). This checkbook system uses soil properties, (texture, thickness of soil layers and water holding capacity of each layer), weather parameters (average daily air temperature, daily solar radiation, date and amount of rain), crop properties (root depth, water use based on growth stage, planting date and emergence date), and irrigation information (rate applied). Neutron probe access tubes will be located within each plot and a neutron probe moisture meter used once a week to reflect moisture deficiency within the checkbook system. All cultural practices (tillage, fertilizer, planting populations, chemical, and fungicide applications) will be the same for the sugarbeet varieties to minimize the effects of variables other than water usage.

Results

Variety A and B were planted 10 May 2010. The emergence date for both varieties was 19 May 2010. The first irrigation occurred on 14 May 2010 (this was a pre-emergence irrigation with all plots receiving .70 inches) with the final irrigation 3 September 2010. There were a total of 19 irrigations from 14 May – 3 September. Rainfall amounts were recorded from 01 May – 01 October and were above normal. The growing season temperatures were average for the 2010 growing season. The irrigation rates of 100%, 66%, 33% and 0% from 14 May – 3 September resulted in 11.4, 7.5, 3.8, and 0.7 inches of water applied respectively. Throughout the growing season the neutron probe readings of top two feet were taken weekly from the different water treatments. The graph shows the variation in soil moisture readings between the four treatments.

Samples were harvested on 21 September 2010. Sugarbeets from ten feet of row were hand harvested and the numbers of beets were counted. These stands (beets/10ft) were used for tallying final plant populations. These samples were analyzed at the Sidney Sugars factory laboratory. Tons per acre, sugar and nitrate percentages were analyzed from these treatments. The results, for 2010, show that there were no significant differences between watering treatments and sugarbeet yield. The only significant difference that was recognized this season was percent sugar. These results were tested using Analysis of Variance at the alpha 0.05 level.

| Treatment | Irrigation Amounts | Rainfall Amounts | Total Water |
|-----------|--------------------|------------------|-------------|
| 0% | 0.7* | 12.49 | 13.19 |
| 33% | 3.8 | 12.49 | 16.29 |
| 66% | 7.5 | 12.49 | 19.99 |
| 100% | 11.4 | 12.49 | 23.89 |

Rainfall amounts and Total Water are for May 1- Oct. 1

*Irrigation amount reflects an after planting irrigation but prior to emergence.

The other treatments also include this 0.7 inches.

Results

| Variety A | | | | |

In the table, numbers followed by the same letter are not significantly different (0.05)
Numbers followed by a different letter are significantly different at alpha 0.05

We are not only looking at water use efficiency in sugarbeets but also looking at potato, wheat, barley, safflower, and lentil systems. In the future we hope to expand on this project and incorporate crops such as corn, soybean and other pulse crops.

¹NDSU Williston Research Extension Center – Nesson Valley

News on Agriculture Diversification/Processing

Chet Hill, NDSU Area Ag Diversification Extension Specialist

After reading last year's update, I thought many things changed during the 2010 crop year. The weather this year went from cool and wet in the spring to warm and still wet conditions during the summer making for crop disease conditions to develop in the region. Many areas in the region received over 20 inches of moisture. A key component of this position is working with the Research Centers in both Williston and Sidney, MT to relay research results to producers and determine the feasibility of different crops and their compatibility in a crop rotation. Both research centers are moving forward in expanding their facilities to better serve our clientele and develop future research that will improve crop production in the region. The irrigation research at Nesson Valley has drastically improved over the last couple of years and now producers need to take advantage of that research.

Here is a summary of some of the projects I have assisted with this past year.

CROPS – What a difficult growing season for producers in the region – frost, cool weather, wet conditions throughout the growing season, and hail to name a few. As a result, many producers saw record yields but I suspect we lost somewhere between 5 – 10 bushels per acre with many of the crops due to the disease conditions that developed during growing season. Pulse crops continue to become stronger in appearance in the region with again lentil acres seeing the biggest growth in acres. Quality concerns during harvest brought discounts to rear its ugly head, making a dismal situation worse because of already low commodity prices at the start of harvest. Prices have rebounded, but many of us do not have the quality to take advantage of the premium side of the markets.

For the producers utilizing irrigation, I have been impressed on all the different crops being produced. This fall roughly 30 new pivots are being constructed in the Mondak region. I receive many calls on if pulse crops and different oilseed crops will perform well under irrigation. Overall, we are still in the learning stage of that question. Pulse and oilseed crops will work but we need to better manage the rotation of those crops and scout the fields more frequently to stay on top of potential disease pressure. Tools are available on the NDSU website to evaluate these conditions. For example, the NDAWN weather system website, allows producers to check weather conditions across the state and determine the risk of disease pressure on crops.

On the dry land side, pulse crop acres expanded dramatically. In MT, lentil acres doubled from 118,000 acres to over 250,000 acres. There is still much discussion with cover crops. I worked with Keith Brown, Divide County Extension Agent, and Jim Hennessy, Mountrail County Extension Agent, on putting together cover crop plots to explore and demonstrate to producers

the possible opportunities with cover crops. Fall seeded cover crops are very marginal in production but spring/summer seeded cover crops yield many benefits. Corn acres continue to expand.

WREC - Neil and I receive many calls asking which variety in durum, spring wheat and barley do well in this region. That is a difficult question to answer because so many factors come into play when selecting a variety – soils and moisture conditions seem to be the most important. Two years ago, I decided to take the off-station data for the different crops and varieties along with the Williston data to develop information that would assist a producer in making variety selections. First, I ranked the varieties (1, 2, 3, etc.) based how on their 3-year average yield or try to fit that variety in the ranking if it only had one or two years of data. Second, I show the 3- year average yields for the different varieties. Each of the tables then have overall averages both in ranking and yield so that one can see how that particular variety stood up among the rest of the varieties. You will find it on the Williston R/E Center website - <http://www.ag.ndsu.edu/WillistonREC/>

Acreages of several crops in the Mondak region can also be found on the website.

PROJECTS – The Mondak Energy Alliance that was created last year made a huge stride this past year. We were able to meet with the Governors of North Dakota and Montana concerning the new oil pipeline that will be constructed through Montana. The governor of Montana has worked with the company constructing the pipeline to include a branch pipeline that will come east to connect into a possible refinery here or transload into the pipeline. Many projects are still on the blackboard including an ethanol plant, diesel topping plant, oil refinery, coal to liquid plant, biodiesel plant and a potato plant.

Horticulture Program

Lorna Bradbury¹

The 2010 growing season was cool, cloudy and damp. May and June had 30 days of rain events with 10 days of significant rainfall. Over the 5 month growing season, from May 1 to September 30 we received 12.44 inches of rain compared to a normal of 10.45 inches. There were no days of 100° F or more and only 9 days when the recorded maximum temperature reached 90° F or more. On July 29, we had a thunderstorm that included 1.23 inches of rain and wind gusts in excess of 50 mph and on August 1, we had another storm that brought another 1.08 inches of rain, wind gusts over 60 mph and quarter size hail. Our last frost date was May 10 with a low temperature of 31° F, and the first killing frost in September was on the 18th with a low of 27° F.

Grapes -- Grapes were fertilized with ammonium sulfate (21-0-0) fertilizer on April 22, 2010, at a rate of about 60 lb N per acre. Petiole samples showed lower N content than last year but still improved from 2008. Soil samples showed N levels still much lower than optimum. Growth of the vines still seemed to be far more dependent on water availability and weed control than on available N.

All varieties except GR7 and Elvira had survived the winter and were alive in the spring of 2010. Pruning started the last week of April and continued as weather permitted through May. Due to the August 1 hail event, much of this year's crop was destroyed. Because the summer was cooler than normal and frost came September 18, there were just not enough heat units to ripen the grapes. We left them on the vines until early to mid-October, hoping to make ice wine but they began to shatter before they could concentrate the sugars enough. We picked the last variety on October 14. Our first snowfall occurred on October 26.

| Grape Cultivar Name | Brix ¹ | pH ¹ | RU ² | Yield (lbs) | | # of producing plants |

¹ Brix and pH measured at harvest.

² RU = Brix * pH² (target for white grapes = 200, for red grapes = 260)

* These cultivars had very few grapes so no Brix or pH was done for them

The St Croix in the depth of planting trial survived the winter, grew rampantly, and set a promising load of fruit. The three year old Edelweiss vines also set some fruit and we were able to sample some of it before the raccoons found them. Between the raccoons and the hail, both the depth of planting and the irrigation trial were wiped out.

Raspberries -- The raspberries did not produce enough berries to record yield data in 2010.

Strawberries -- This year we covered the strawberries – first with floating row covers, then with bird netting and surrounded the bed with rabbit fence. We started picking June 24 and ended July 26. Cavendish yielded the most berries and was rated the highest by our taste testers.

| Strawberry Variety Trial 2010 | | | | | | | | |

LSD 5% - NS

AAS Flowers -- Our first year as an official All America Selections Display Garden was a success. The plants had a slow start in the cool cloudy early summer, but had filled in and were in full bloom when the hailstorm struck. They looked quite shattered after that, but all recovered and bloomed nicely until our first frost.

Extension Vegetable Program -- We took part in the NDSU Extension garden research project and enjoyed taste testing and rating the many vegetable varieties that were supplied to us by Extension Horticulturist Tom Kalb. We tested several varieties of beans, carrots, cucumbers, mizuna, kohlrabi, lettuce, melons, cantaloupe, spinach, squash, and watermelon. The results of the home garden vegetable trials will be available at the following web site www.dakotagardener.com/trials/index.html

Sweet Potatoes -- Sweet potato varieties Beauregard, Georgia Jet, O'Henry, Centennial, and Vardaman were planted on June 1 at Nesson Valley under sprinkler irrigation in a randomized complete block design. They were harvested September 17 just before our first killing frost. The roots were cured and then graded for size. Beauregard produced the most quantity of roots but the only variety that met the sizing criteria for fries was Georgia Jet.

Georgia Jet Sweet Potato Yield 2010

| | Rep 1 | Rep 2* | Rep 3 | Rep 4 |
|------------|-------|--------|-------|-------|
| # of Roots | 5 | 0 | 14 | 4 |
| Weight | 5.2 | 0.0 | 12.1 | 3.1 |

* Rep 2 did not have any plants growing in it.

Hops -- Four rhizomes each of five cultivars of hops, Cascade, Centennial, Chinook, Glacier, and Willamette were planted in 2009 and in 2010 all had survived the winter with the help of a layer of straw mulch. They all produced hops that were harvested in mid-September. The flowers were then dried in a dryer oven, placed in plastic bags and stored in a freezer.

Tomato Demonstration -- We planted 66 Celebrity tomato plants and mulched them with 10 different types of mulch from plastics to natural materials, leaving one set of 6 with no mulch treatment as a control. We treated them all the same after that with drip irrigation and a small amount of liquid fertilizer. The whole planting was badly damaged by hail on August 1, but we were still able to harvest a small number of tomatoes from each plot. The mulch that produced the healthiest tomato plants and the most fruit was a thick layer of grass clippings. The tomatoes that looked the worst and produced the least fruit were mulched with pine needles, straw or woos chips.

Tomato Mulch Demonstration 2010 Williston Research Extension Center

Composition and Production of Perennial Grasses for Biofuel Production in Central and Western North Dakota

Paul E. Nyren² Qingwu Xue¹, Ezra Aberle³, Gordon Bradbury⁴ Eric Eriksmoen⁵, Mark Halverson⁶, Kris Nichols⁷ and Mark Liebig⁷, Anne Nyren², Bob Patton².

A ten-year field study was initiated in 2006 to evaluate ten entries of perennial grasses and mixtures in two harvest scenarios (annual and biennial). The experimental design was a randomized complete block design with 4 replications. The plots were seeded at five locations in NDSU Research Extension Centers across central and western North Dakota. Among the five locations, long term growing season precipitation varies from 12.5" at Williston to 17" at Carrington. However, the variation of mean temperature is small across locations from west to east. At the Williston location, the plots were seeded and managed under both dryland and irrigated conditions. The plots at the other four locations were managed under dryland condition. In total, the grasses/mixtures were grown in six environments.
