## YEAR/PROJECT: 1996/755

## TITLE: Safflower Plant Population Study - Dryland

PERSONNEL: Leon Welty, NWARC
Louise Prestbye, NWARC

On May 21, 1996 'Centennial' safflower was seeded in 6-and 12 -inch rows at rates of $10,20,30$, and 40 lbs . PLS/acre. Stands (\# of plants/ft²) increased as seeding rate increased. The 6 -inch spacing produced slightly denser stands than the 12inch spacing. Weed emergence and safflower plant vigor were not influenced by either seeding rate or row spacing. Plant height at harvest decreased slightly as seeding rate increased. The $40-\mathrm{lb}$ seeding rate seemed to slow maturity.

The trial was harvested Aug. 15 when $4-24 \%$ of the flowers had wilted. Neither seeding rate nor row spacing produced significant differences in forage yield. The lack of response indicates that $10 \mathrm{lbs} /$ acre PLS is sufficient for either 6 - or 12 -inch rows.

Protein and fiber content is being analyzed. Since stand density did not affect weed emergence or stand vigor, the only advantage to higher seeding rates could be the retardation of maturity and higher forage quality.
